Project Name	Personalised Networking Assistant
Maximum Marks	4 Marks

Solution Architecture

The Personalized Networking Assistant is designed using a modular client-server architecture that connects business requirements with AI-based technology solutions. The solution enables users to enter event details and personal interests through the Streamlit interface, while the FastAPI backend processes the input using KeyBERT with DistilBERT to generate personalized conversation topics. The generated information is verified using the Wikipedia API, and the results are displayed to the user. Conversation history and feedback are stored in a local JSON database. This architecture provides a clear structure for the application, defines the major functional components, supports future enhancements, and ensures an efficient, scalable, and maintainable solution.
